P/D hand-off with NIXL: it works, but slowly

Prefill on replica a, decode on replica b; 4 × 10K-token documents; the client passes the hand-off details

test client | vLLM | KV transfer | the bottleneck

UCX wanted CUDA IPC (GPU to GPU), but the two replicas live in separate HAMi containers: no IPC between them → falls back to TCP ~206 MB per call at ~92 MB/s

decode's first token after 2.2–2.5 s vs 0.37 s to simply re-read the document → 6× slower. Answers identical: GO

First attempt crash-looped: hybrid (GDN) models need VLLM_SSM_CONV_STATE_LAYOUT=DS for NIXL. Fixed, then GO.
